

# CGHnormaliter Package (Version 1.2.0)

Thomas W. Binsl, Bart P.P. van Houte, Hannes Hettling

April 22, 2010

## 1 Introduction

This package contains an implementation of the CGHnormaliter strategy for improved normalization of dual-channel array Comparative Genomic Hybridization (aCGH) data displaying many copy number imbalances. The key idea of our method is that temporary exclusion of aberrations from the data allows for a more appropriate calculation of the LOWESS regression curve. As a result, after normalization, the  $\log_2$  intensity ratios of the normals will generally be closer to zero and better reflect the biological reality. We coin this normalization strategy ‘local-LOWESS’ since only a subset of the  $\log_2$  ratios is considered in the LOWESS regression.

The strategy can be summarized as follows. Initially the  $\log_2$  intensity ratios are segmented using DNACopy [4]. The segmented data are then given as input to a calling tool named CGHcall [2] to discriminate the normals from gains and losses. These normals are subsequently used for normalization based on LOWESS. These steps are then iterated to refine the normalization. An overview is given in Figure 1. For more detailed information we refer to the publication of our method [3].

## 2 Data format

The input should be either a `data.frame` or the file name of a tabseparated text file (text files must contain a header). The first four columns should describe the clone and its position on the genome:

1. ID : The unique identifiers of array elements.
2. Chromosome : Chromosome number of each array element.
3. Start : Chromosomal start position in bp of each array element.
4. End : Chromosomal end position in bp of each array element.

The start and end positions must be numeric. The next columns hold the actual data. For each sample in the experiment, there must be two adjacent

Figure 1: Overview of the CGHnormaliter method.

columns with the *test* and *reference* intensities, respectively. All entries must be delimited by tabs, and missing entries must be denoted with *NA* or by an empty value. Below, an example is given of a correctly formatted data file or data.frame containing measurements on 7 clones in 2 samples.

ID	Chromosome	Start	End	Case1.test	Case1.ref	Case2.test	Case2.ref
RP11-34P13	1	1	254479	279	294	NA	NA
RP11-379K15	1	95421	244136	1815	2269	2793	3996
RP11-776O18	1	357737	465038	387	349	429	362
RP11-45C18	1	579118	696613	786	734	900	735
RP11-242B5	1	606617	711982	2955	4158	4478	5229
RP13-586C17	1	619355	783174	NA	NA	823	841
RP11-414L23	1	658751	846904	630	937	959	744

### 3 Example

First, we load the example Leukemia dataset [1] which is contained in the CGH-normaliter package:

```

> library(CGHnormaliter)
> data(Leukemia)

```

Next, we run the CGHnormaliter routine on the first three chromosomes of the Leukemia data, with a maximum of 3 iterations:

```

> result <- CGHnormaliter(Leukemia, nchrom = 3)

```

```

CGHnormaliter -- Running an initial segmentation and calling
Start data segmentation ..
Analyzing: Sample.1
Analyzing: Sample.2

```

```

Analyzing: Sample.3
Start data calling ...
CGHnormaliter -- Iteration # 1
CGHnormaliter -- Mean normalization shift per sample:
  Case1.test_Case1.ref : 0.4285348
  Case2.test_Case2.ref : 0.4598285
  Case3.test_Case3.ref : 0.3356325
Start data segmentation ..
Analyzing: Sample.1
Analyzing: Sample.2
Analyzing: Sample.3
Start data calling ...
CGHnormaliter -- Iteration # 2
CGHnormaliter -- Mean normalization shift per sample:
  Case1.test_Case1.ref : 0.002363037
  Case2.test_Case2.ref : 0.002599055
  Case3.test_Case3.ref : 0.002958949
CGHnormaliter -- Reached convergence. Running a final segmentation and calling...
Start data segmentation ..
Analyzing: Sample.1
Analyzing: Sample.2
Analyzing: Sample.3
Start data calling ...
CGHnormaliter -- FINISHED

```

Now we can access several fields of the `result` object, for example:

```

> normalized.data <- copynumber(result)
> segmented.data <- segmented(result)
> called.data <- calls(result)

```

To visualize the results per sample, the `plot` function of the `CGHcall` package can be used. In Figure 2 we plot the results for the second sample:

```

> plot(result[, 2])

```

Plotting sample `Case2.test_Case2.ref`

Finally, the package provides the function `CGHnormaliter.write.table` to save the normalized data into a tabdelimited plain text file:

```

> CGHnormaliter.write.table(result)

```

Saving normalized log<sub>2</sub> ratios to file: `normalized.txt`

Plotting sample Case2.test\_Case2.ref

Figure 2: Results of the CGHnormaliter normalization for the second Leukemia sample.
