

# Package ‘spliceSites’

April 23, 2016

**Type** Package

**Title** A bioconductor package for exploration of alignment gap positions from RNA-seq data

**Version** 1.8.3

**Date** 2012-10-28

**Author** Wolfgang Kaisers

**Maintainer** Wolfgang Kaisers <kaisers@med.uni-duesseldorf.de>

**Description** Performs splice centered analysis on RNA-seq data.

**License** GPL-2

**Depends** methods,rbamtools (>= 2.14.3),refGenome (>= 1.6.0),Biobase,Biostrings (>= 2.28.0)

**Imports** BiocGenerics,doBy,seqLogo,IRanges

**Collate** allClasses.r allGenerics.r c-methods.r dim-methods.r head-methods.r show-methods.r spliceSites.r

**biocViews** RNASeq, GeneExpression, DifferentialExpression, Proteomics

**NeedsCompilation** yes

---

spliceSites-package     *Calculate information on splice-sites from gapped alignments in RNA-seq data.*

---

## Description

The package defines 'cRanges' the (centered ranges) class which represents a genomic range that contains a highlighted position (center): This will usually be the boundary between an exon and an intron. The second defined type is the class 'gapSites' which represents two exonic regions divided by a gap (usually an intron). There are subclasses which additionally contain DNA or AA sequences.

## Details

Package: spliceSites  
Type: Package  
Version: 1.0  
Date: 2012-10-28  
License: GPL-2  
Depends: methods,rbamtools,refGenome,Biobase,BiocGenerics,Biostrings,seqLogo

## Author(s)

## Examples

```
bam <- system.file("extdata", "rna_fem.bam", package="spliceSites")
reader <- bamReader(bam, idx=TRUE)
ga <- alignGapList(reader)
bamClose(reader)
dnafile <- system.file("extdata", "dna_small.RData", package="spliceSites")
load(dnafile)
ucf <- system.file("extdata", "uc_small_junc.RData", package="spliceSites")
ucj <- loadGenome(ucf)
annotation(ga) <- annotate(ga, ucj)
ga
```

---

aaGapSites-class      *Class "aaGapSites"*

---

### Description

Contains gapAligns data and a AAStringSet.

### Objects from the Class

Objects can be created by calls of the form `new("aaGapSites", ...)`.

### Slots

`seq`: "AAStringSet": Contains amino acid sequences.

`nAligns`: "numeric": Contains total number of aligns.

`nAlignGaps`: "numeric": Contains total number of align gaps.

`dt`: "data.frame": Contains data for all gap sites.

### Extends

Class "[gapSites](#)", directly.

### Methods

**head** signature(`x = "aaGapSites"`): Returns the first lines of object.

**show** signature(`object = "aaGapSites"`): Returns the last lines of object.

**truncateSeq** signature(`x="caRanges"`, `rme=TRUE`, `trunc=42L`): Truncates contained sequence when character (given by ASCII code in `trunc`). The default (42L) encodes for character '\*' which indicates stop-codon.

**trypsinCleave** signature(`x = "caRanges"`, `minLen = 5`): Performs in silico trypsinization of contained sequence. The sequence fragment which contains the (position depicted) exon-intron boundary is returned. Datasets for which the truncated sequence is shorter than `minLen` are excluded.

**write.files** signature(`x = "caRanges"`): Exports contained data into "csv" file.

### Author(s)

Wolfgang Kaisers

**Examples**

```

# A) Read gap-sites from BAM-file
bam <- system.file("extdata", "rna_fem.bam", package="spliceSites")
reader <- bamReader(bam, idx=TRUE)
ga <- alignGapList(reader)
bamClose(reader)

# B) Load reference dna
dnafile <- system.file("extdata", "dna_small.RData", package="spliceSites")
load(dnafile)

# C) Calculate cross junctional ranges
lrj <- lrJunc(ga, lfeatlen=6, rfeatlen=6, strand='+')
lr1 <- lrCodons(lrj, frame=1, strand='+')
lr2 <- lrCodons(lrj, frame=2, strand='+')
lr3 <- lrCodons(lrj, frame=3, strand='+')
lr <- c(lr1, lr2, lr3)

# D) Add DNA-sequence
lrd <- dnaGapSites(lr, dna_small)

# E) Translate DNA to amino acid
lra <- translate(lrd)

```

---

addGeneAligns	<i>Reads a bamRange object for a given bamReader, refGenome and gene name.</i>
---------------	--

---

**Description**

Locates gene in genome via refGenome and reads a bamRange from the determined region.

**Usage**

```
addGeneAligns(x)
```

**Arguments**

x gapSites. The result contains a copy of the passed object.

**Details**

The function adds a gene\_aligns column to the contained data.frame.

**Value**

gapSites

**Author(s)**

Wolfgang Kaisers

**Examples**

```
# A) Read gapSites
bam <- system.file("extdata", "rna_fem.bam", package="spliceSites")
reader <- bamReader(bam, idx=TRUE)
ga <- alignGapList(reader)
bamClose(reader)

# B) Annotate
ucf <- system.file("extdata", "uc_small_junc.RData", package="spliceSites")
ucj <- loadGenome(ucf)
annotation(ga) <- annotate(ga, ucj)

# C) align part
gal <- addGeneAligns(ga)
gal
```

addHbond

---

*Class "hbond": Provides data and functions for calculation of HBond scores for 5' splice-sites.*

---

**Description**

The addHbond methods add HBond scores to gapSites and cdRanges objects. HBond scores provide a measure for the capability of a 5' splice-site to form H-bonds with the U1 snRNA. The function requires at least 3 exon nucleotides and 8 intron nucleotides. The first two intron nucleotides are expected to be 'GT' (for other values the returned score will be 0). The routine equally accepts upper and lower case characters.

**Usage**

```
addHbond(x, dna)
```

**Arguments**

x	gapSites. The object to which HBond scores are added.
dna	DNAStrngSet. Reference sequence identifier.

**Details**

In cdRanges objects, the function adds a hbond column. In gapSites objects, the function adds a lhbond (left side) and a rhbond (right side) column. The lhbond values always assume '+'-strand (because HBond works on the 5' side). The rhbond values always assume '-'-strand. Therefore, there will be discrepancies in the output of write.annDNA.tables because the leftseq and rightseq sequences are reverse-complemented according to the strand column: The xhbond may be > 0 without GT at position 4 (but with AC at position 7).

**Author(s)**

Wolfgang Kaisers

**References**[http://www.uni-duesseldorf.de/rna/html/hbond\\_score.php](http://www.uni-duesseldorf.de/rna/html/hbond_score.php)**Examples**

```
# A) Read gapSites
bam<-system.file("extdata","rna_fem.bam",package="spliceSites")
reader<-bamReader(bam,idx=TRUE)
ga<-alignGapList(reader)
bamClose(reader)

# B) Load DNA
dnafile<-system.file("extdata","dna_small.RData",package="spliceSites")
load(dnafile)

# C) HBond
gab<-addHbond(ga,dna_small)

# D) cdRanges
lj<-lJunc(ga,featlen=3,gaplen=8,strand='+')
ljd<-dnaRanges(lj,dna_small)
ljdh<-addHbond(ljd)
```

addMaxEnt

---

*addMaxEnt: Extract subset of data contained in given range given object.*

---

**Description**

addMaxEnt adds new columns to object data which contain MaxEnt-Score derived values. mxe\_ps5 contains score5 values for left align-gap (exon-intron) boundary (i.e. assumed to reside on '+'-strand. mxe\_ps3 contains score3 (maxent) values for right align-gap (intron-exon) boundary (i.e. assumed to reside on '+'-strand).

mxe\_ms5 contains score5 values for right align-gap (exon-intron) boundary on reverseComplement transformed sequence (i.e. assumed to reside on '-'-strand).

mxe\_ms3 contains score3 values for left align-gap (intron-exon) boundary on reverseComplement transformed sequence (i.e. assumed to reside on '-'-strand).

From these values, s3strand, s5strand and meStrand are derived: s3strand is '+' when mxe\_ps5 >= mxe\_ms5 and '-' otherwise; s3strand is '+' when mxe\_ps3 >= mxe\_ms3 and '-' otherwise.

meStrand equals s5strand when s5strand=s3strand and '\*' otherwise.

The function setMeStrand copies existing meStrand values into strand column (and throws an error when meStrand does not exist).

**Usage**

```
addMaxEnt(x,dna,maxent,digits=1)
```

**Arguments**

x	gapSites.
dna	DNAStrngSet. Reference sequence identifier.
maxent	maxEnt. Contains score table which are internally used by score3 and score5 methods.
digits	Numeric. Default value: 1. Internally calculated maxent scores are rounded to given number of decimal places.

**Value**

gapSites

**Author(s)**

Wolfgang Kaisers

**Examples**

```
# A) Read gapSites
bam<-system.file("extdata","rna_fem.bam",package="spliceSites")
reader<-bamReader(bam,idx=TRUE)
ga<-alignGapList(reader)
bamClose(reader)

# B) Load DNA
dnafile<-system.file("extdata","dna_small.RData",package="spliceSites")
load(dnafile)

# C) maxEnt
mes<-load.maxEnt()
gae<-addMaxEnt(ga,dna_small,mes)
getMeStrand(gae)
sae<-setMeStrand(gae)
```

---

alt\_X\_ranks

*alt\_left\_ranks and alt\_right\_ranks functions: Identification of alternative splicing events from gapped alignments.*

---

**Description**

alt\_X\_ranks covers the functions alt\_left\_ranks and alt\_right\_ranks. Both functions identify alternative splice-sites. alt\_left\_ranks finds sites which share the same rstart value (on the same seqid). alt\_right\_ranks finds sites which share the same lend value (on the same seqid). alt\_ranks combines the results of both functions together with seqid, lend and rstart values in one table.

**Usage**

```
alt_left_ranks(x)
```

**Arguments**

x gapSites. Object for which alternative ranks are calculated

**Details**

The function `alt_left_ranks` groups align-gaps (splice-sites) which share identical `rstart` position and have different `lend` position. Each Group is assigned a unique `alt_id` (integer value beginning from 1). The first column in the returned `data.frame` is an `id`-column which facilitates table merging with the source table. The result has the same number of rows as the source and the `id`-column.

**Value**

`data.frame`. The table contains the columns `nr_alt`, `alt_id`, `id`, `diff_ranks` and `gap_diff`.

**Author(s)**

Wolfgang Kaisers

**Examples**

```
# A) Read gapSites
bam<-system.file("extdata","rna_fem.bam",package="spliceSites")
reader<-bamReader(bam,idx=TRUE)
ga<-alignGapList(reader)
bamClose(reader)

# B) alt_ranks
alr<-alt_left_ranks(ga)
ar<-alt_ranks(ga)
```

---

annGapSites-class      *Class "annGapSites"*

---

**Description**

Contains data from align gaps together with annotation data (and optional data about alternative splice positions). Objects of this class are returned from the annotation member function for class `gapSites`.

**Details**

`plot_diff` plots tabulated distance between inner gap-site border and annotated exon-intron boundaries.

## Objects from the Class

Objects can be created by calls of the form `annotation` on `gapSites` objects.

## Slots

`nAligns`: Object of class "numeric" Total number of aligns.

`nAlignGaps`: Object of class "numeric" Total number of gapped aligns.

`dt`: "data.frame". Contains gap-positions, annotation data and optional alternative position data.

`annotation`: "data.frame". Contains annotation data.

`profile`: "data.frame". Contains descriptive data for source probes (BAM-files).

## Extends

Class "`gapSites`", directly.

## Methods

`as.data.frame` signature(`x = "annGapSites"`): Returns the contained data.

## Author(s)

Wolfgang Kaisers

## Examples

```
# A) Read gapSites from BAM
bam <- system.file("extdata", "rna_fem.bam", package="spliceSites")
reader <- bamReader(bam, idx=TRUE)
ga <- alignGapList(reader)
bamClose(reader)

# B) Load annotation data
ucf <- system.file("extdata", "uc_small_junc.RData", package="spliceSites")
ucj <- loadGenome(ucf)

# C) Add Annotation
annotation(ga) <- annotate(ga, ucj)

# D) Retrieve annotation
aga <- annotation(ga)
aga

# D) plot_diff
aga <- annotation(ga)
plot_diff(aga)
```

---

`annotate-ExpressionSet`*Adds annotation data to existing ExpressionSet (created by readExpSet)*

---

## Description

Reads featureData from incoming Expression set which should contain range data on embedding exons for gap-sites. The annotate function then overlaps the ranges with given annotation data. The result of overlapping is written into a AnnotatedDataFrame.

## Arguments

object	ExpressionSet
genome	refGenome

## Value

AnnotatedDataFrame

## Author(s)

Wolfgang Kaisers

## Examples

```
# A) Names of BAM-files
bam <- character(2)
bam[1] <- system.file("extdata", "rna_fem.bam", package="spliceSites")
bam[2] <- system.file("extdata", "rna_mal.bam", package="spliceSites")

# B) Experiment Profile
prof <- data.frame(gender=c("f", "m"))
meta <- data.frame(labelDescription=names(prof), row.names=names(prof))
pd<-new("AnnotatedDataFrame", data=prof, varMetadata=meta)

# C) Read ExpressionSet
es <- readExpSet(bam, phenoData=pd)

# D) Annotate ExpressionSet
ucf <- system.file("extdata", "uc_small.RData", package="spliceSites")
uc <- loadGenome(ucf)
juc <- getSplICETable(uc)
ann <- annotate(es, juc)
```

---

annotation

*Annotation functions for gapSites objects*

---

## Description

The `annotate` function takes a `gapSites` and a `refGenome` object and returns a list which additionally contains a 'class' attribute 'annotationResult'. The object is intended as input for the annotation member function of class `gapSites`. The annotation member functions act as writing and reading accessor for annotation data inside `gapSites` objects.

## Usage

```
annotate(object, junc)
```

## Arguments

`object` [gapSites]. Align-gap data for which annotations are provided via overlap.  
`junc` [refJunctions]. Object which provides annotated splice site positions.

## Details

The annotation reading accessor takes a `gapSites` object and returns a `annAlignGaps` object. The annotation writing accessor takes a `gapSites` and a `annotationResult` object and copies the contained table into the annotation slot of the `gapSites` object.

## Value

`annAlignGaps`

## Author(s)

Wolfgang Kaisers

## Examples

```
# A) Create gapSites object
bam <- system.file("extdata", "rna_fem.bam", package="spliceSites")
reader <- bamReader(bam[1], idx=TRUE)
ga <- alignGapList(reader)
bamClose(reader)

# B) Read refGenome object
ucf <- system.file("extdata", "uc_small_junc.RData", package="spliceSites")
ucj <- loadGenome(ucf)

# C) Add annotation data
annotation(ga) <- annotate(ga, ucj)
```

---

as.data.frame-methods    as.data.frame *Returning content of data.frame.*

---

**Description**

Methods for function as.data.frame

**Methods**

signature(x = "gapSites") Method for 'gapSites'.

signature(x = "annGapSites") Method for 'annGapSites'.

---

c-methods

*Coercing functions c.*

---

**Description**

Coerce objects by binding contained data.

**Methods**

signature(x = "cRanges") Method for 'cRanges'.

signature(x = "gapSites") Method for 'gapSites'.

---

caRanges-class

*Class "caRanges"*

---

**Description**

"caRanges" Objects that contain a centered genomic range and amino acid sequences.

**Objects from the Class**

Objects are usually created from objects of class "cdRanges" by the "translate" function.

**Slots**

dt: Object of class "data.frame". Contains the columns "seqid", "start", "end", "strand", "position", "id", "frame"

seq: Object of class "AAStringSet". Contains amino-acid-sequence of ranges described in dt.

**Extends**

Class "[cRanges](#)", directly.

**Methods**

- c** signature(x = "caRanges"): Generic combining for caRanges objects.
- getSequence** signature(x="caRanges"): Returns contained sequence (DNAStrngSet).
- head** signature(x = "aaGapAligns"): Returns the first lines of object.
- show** signature(object = "aaGapAligns"): Returns the last lines of object.
- truncateSeq** signature(x="caRanges", rme=TRUE, trunc=42L): Truncates contained sequence when character (given by ASCII code in trunc). The default (42L) encodes for character '\*' which indicates stop-codon.
- trypsinCleave** signature(x = "caRanges", minLen = 5): Performs in silico trypsinization of contained sequence. The sequence fragment which contains the (position depicted) exon-intron boundary is returned. Datasets for which the truncated sequence is shorter than minLen are excluded.
- write.files** signature(x = "caRanges"): Exports contained data into "csv" file.

**Author(s)**

Wolfgang Kaisers

**See Also**

cRanges

**Examples**

```
# A) Read gapSites object
bam<-system.file("extdata","rna_fem.bam",package="spliceSites")
reader<-bamReader(bam,idx=TRUE)
ga<-alignGapList(reader)
bamClose(reader)
ga
# B) Create cRanges object
lj<-lJunc(ga,featlen=21,gaplen=21,strand='+')
ljc<-lCodons(lj,frame=1,keepStrand=TRUE)
dnafile<-system.file("extdata","dna_small.RData",package="spliceSites")
load(dnafile)
# C) Add DNA sequence
cdr<-dnaRanges(ljc,dna_small)
# D) Translate into AA sequence
ar<-translate(cdr)
# E) Truncate and cleave...
tra<-truncateSeq(ar)
tyc<-trypsinCleave(tra)
```

---

cdRanges-class	Class "cdRanges"
----------------	------------------

---

**Description**

"cdRanges" Objects that contain centered Ranges (exon-intron junctions) and dna-sequences.

**Objects from the Class**

Objects are usually created from "cRanges" with the function "dnaRanges".

**Slots**

**dt:** Object of class "data.frame". Contains the columns "seqid", "start", "end", "strand", "position", "id", "frame".

**seq:** Object of class "DNAStrngSet". Contains the dna-sequence of ranges described in dt.

**Extends**

Class "cRanges", directly.

**Methods**

**c** signature(x = "cdRanges"): Generic combining for cdRanges objects.

**getSequence** signature(x="cdRanges"): Returns contained sequence (DNAStrngSet).

**head** signature(x = "cdRanges"): Prints first items from object.

**initialize** signature(.Object = "cdRanges"): Create an instance of class using new.

**seqlogo** signature(x = "cdRanges"): Show a seqlogo of contained sequences

**translate** signature(x = "cdRanges"): Translates dna-sequence into amino-acid-sequence. Returns an object of class "caRanges".

**Author(s)**

Wolfgang Kaisers

**See Also**

cRanges

**Examples**

```
# A) Read gapSites object
bam<-system.file("extdata","rna_fem.bam",package="spliceSites")
reader<-bamReader(bam,idx=TRUE)
ga<-alignGapList(reader)
bamClose(reader)
ga
# B) Create cRanges object
```

```

ljc<-lCodons(ljc, frame=1, keepStrand=TRUE)
dnafile<-system.file("extdata", "dna_small.RData", package="spliceSites")
load(dnafile)
# C) Add DNA sequence
cdr<-dnaRanges(ljc, dna_small)
# D) seqLogo ...
seqlogo(cdr)

```

---

countByGeneName	<i>Reads align number for selected gene from multiple BAM-files.</i>
-----------------	--

---

### Description

Opens multiple BAM-files and reads aligns for selected gene for each file. The function counts the tag-selected value which either is a BAM-cigar operation (like "N" or "M") or the total number of aligns.

### Usage

```
countByGeneName(object, infiles, idxInfiles=paste(infiles, ".bai", sep=""), gene, tag="N")
```

### Arguments

object	Object of class "refGenome"
infiles	Vector of BAM-files
idxInfiles	(Optional) Vector of BAM-index files.
gene	Gene name
tag	Character. Passed to (rbamtools) 'bamCountAll' function. Default value is "N". Other accepted values include "nAligns", "M", "I", "D".

### Details

countByGeneName first uses the extractByGeneName and getGenePositions from 'refGenome' in order to calculate coordinates from the given gene name. Then for each given BAM-file name, the functions calls the bamCount function and returns a vector with a count value for each given file. Internally countByGeneName also checks for existing BAM-index file and tries to create index files which do not exist.

### Value

Numeric vector. Length equals number of BAM-input files.

### Author(s)

Wolfgang Kaisers

**Examples**

```
# A) Read filenames
ucf<-system.file("extdata","uc_small.RData",package="spliceSites")
uc<-loadGenome(ucf)
bam<-character(2)
bam[1]<-system.file("extdata","rna_fem.bam",package="spliceSites")
bam[2]<-system.file("extdata","rna_mal.bam",package="spliceSites")
# B) count
countByGeneName(uc,bam,gene="WASH7P",tag="N")
countByGeneName(uc,bam,gene="WASH7P",tag="nAligns")
```

---

cRanges-class

*Class "cRanges": Centered ranges.*

---

**Description**

"cRanges" Objects that contain centered genomic ranges. The center position marks a prominent position inside the range, generally an exon-intron junction. Position values represent the 0-based position of last exon nucleotide.

**Objects from the Class**

Objects can be created by calls of the form `new("cRanges", seqnames, start, end, width, strand, position, id)`.

**Slots**

**dt**: Object of class "data.frame". The data.frame contains the columns id, seqnames, start, end, width, strand and position. Each row contains data for one centered range.

**Methods**

**as.data.frame** signature(x = "cRanges"): Returns a copy of the contained data inside a data.frame object.

**c** signature(x = "cRanges"): Generic combining for cRanges objects.

**count** signature(x = "cRanges"): Returns the number of contained ranges (number of rows).

**dim** signature(x = "cRanges"): Returns the dim of the contained data.frame.

**dnaRanges** signature(x = "cRanges", dnaset="DNAStrngSet", useStrand="logical", removeUnknownStrand=logical): Takes a cRanges object and a DNAStrngSet (a reference sequence) and adds the appropriate DNA sequence to the genomic ranges. Returns a cdRanges object.

**end** signature(x = "cRanges"): Returns end column of data.

**head** signature(x = "cRanges", n="numeric", digits="numeric"): Returns first n (default: n=6) lines of contained data.frame.

**id** signature(x = "cRanges"): Returns id column from contained data.frame.

**initialize** signature(.Object = "cRanges"): Generic class initialisation method.

**lCodons** signature(x = "cRanges", frame="numeric", keepStrand="logical"): Returns cRanges object which represents ranges truncated to codon size. When 'keepStrand' is set to FALSE, strand is set to '+'. The intention is that appended DNA sequences which then can be translated into amino acids.

**rCodons** signature(x = "cRanges", frame="numeric", keepStrand="logical"): Returns cRanges object which represents ranges truncated to codon size. When 'keepStrand' is set to FALSE, strand is set to '+'. The intention is that appended DNA sequences which then can be translated into amino acids.

**seqid** signature(x = "cRanges"): Returns vector with seqid's.

**show** signature(object = "cRanges"): Generic print function.

**sortTable** signature(x="cRanges"): Sort contained tables by seqid, lend and rstart.

**start** signature(x = "cRanges"): Returns start column from contained data.frame.

**strand** signature(x = "cRanges"): Returns strand column from contained data.frame.

**width** signature(x = "cRanges"): Returns width of contained ranges (=end-start+1).

dim-methods

dim: *Return dimensions of contained data.frame.*

---

### Description

Methods for function dim

### Methods

signature(x = "cRanges") Method for 'cRanges'.  
signature(x = "gapSites") Method for 'gapSites'.

---

dnaGapSites-class

Class "dnaGapSites"

---

### Description

dnaGapSites contains all data which is stored in objects of class "gapSites" plus additional DNA sequences in the "seq" slot.

### Objects from the Class

Objects are usually created from gapSites via dnaGapSites.

### Slots

seq: "DNAStrngSet". Contains DNA sequence.  
nAligns: code"numeric". Contains total number of aligns.  
nAlignGaps: "numeric". Contains total number of align gaps.  
dt: code"data.frame". Contains data on gap-sites.

### Extends

Class "[gapSites](#)", directly.

### Methods

**head** signature(x = "dnaGapSites"): Returns head of dt.  
**seqlogo** signature(x = "dnaGapSites"): Prints seq-logo of stored dna-sequence.  
**show** signature(object = "dnaGapSites"): Prints head of dt.  
**translate** signature(x = "dnaGapSites"): Returns an object of class aalignGaps by translating seq into amino acids.

gapSites

**Examples**

```

# A) Read gapSites
bam<-system.file("extdata", "rna_fem.bam", package="spliceSites")
reader<-bamReader(bam,idx=TRUE)
ga<-alignGapList(reader)
# B) Load DNA sequence
dnafile<-system.file("extdata","dna_small.RData",package="spliceSites")
load(dnafile)
# C 1) Add DNA
dga<-dnaGapSites(ga,dna_small)
dga
# C 2) Calculate codon positions
lrj<-lrJunc(ga,lfeatlen=6,rfeatlen=6,strand='+')
lrc<-lrCodons(lrj,frame=1,strand='+')
# D) Add DNA sequence and translate
lrd<-dnaGapSites(lrc,dna_small)
lra<-translate(lrd)
lra

```

---

dnaRanges	<i>Reads a bamRange object for a given bamReader, refGenome and gene name.</i>
-----------	--

---

**Description**

Locates gene in genome via refGenome and reads a bamRange from the determined region.

**Usage**

```
dnaRanges(x,dnaset,useStrand=TRUE,removeUnknownStrand=TRUE,verbose=TRUE,...)
```

**Arguments**

x	cRanges. Range-data will be copied from this object.
dnaset	DNAStrngSet. Contains the reference sequence from which the DNA-sequence is extracted.
useStrand	logical. When TRUE, sequences for which strand='-' are reverse-complemented.
removeUnknownStrand	logical. When TRUE, sequences for which strand='*' are removed.
verbose	logical. Determines amount of console output during routine runtime.
...	Optional additional arguments (currently unused).

**Value**

cdRanges

**Author(s)**

Wolfgang Kaisers

**Examples**

```

bam<-system.file("extdata","rna_fem.bam",package="spliceSites")
reader<-bamReader(bam,idx=TRUE)
ga<-alignGapList(reader)
bamClose(reader)
lj<-lJunc(ga,featlen=6,gaplen=6,strand='+')
dnafile<-system.file("extdata","dna_small.RData",package="spliceSites")
load(dnafile)
ljd<-dnaRanges(lj,dna_small)
seqlogo(ljd)

```

---

extractByGeneName	<i>extractByGeneName: Extract subset for sites which lie in range(s) defined by given gene list.</i>
-------------------	--

---

**Description**

The function takes a 'cRanges' object (or derived) and searches inside of given 'refGenome' object for gene names. From identified gene-name matches genomic target regions can be defined for which in turn the contained sites are extracted.

**Usage**

```
extractByGeneName(object, geneNames, src, ...)
```

**Arguments**

object	gapSites or cRanges (or derived). Object inside which the data is searched for.
geneNames	Character. Vector of gene names for which data is to be extracted.
src	refGenome. Contains gene annotation (for conversion of gene-name to genomic coordinates).
...	(currently unused)

**Details**

The function internally calls 'extractByGeneName' on 'refGenome'. This function also prints out non matching gene names. On the result, the function calls 'getGenePositions' from which the genomic regions can be extracted. For each gene, data is extracted via 'extractRange' and the resulting objects are then concatenated.

**Value**

Same type as object

**Author(s)**

Wolfgang Kaisers

**Examples**

```
# A) Read gapSites from BAM
bam<-system.file("extdata","rna_fem.bam",package="spliceSites")
reader<-bamReader(bam,idx=TRUE)
ga<-alignGapList(reader)
bamClose(reader)
# B) Load DNASTringSet
dnafile<-system.file("extdata","dna_small.RData",package="spliceSites")
load(dnafile)
# C) load refGenome
ucf<-system.file("extdata","uc_small.RData",package="spliceSites")
uc<-loadGenome(ucf)
# D) For cRanges
lj<-lJunc(ga,featlen=6,gaplen=3,strand='+')
ljw<-extractByGeneName(lj, geneNames="WASH7P", src=uc)
# E) For cdRanges
ljc<-lCodons(lj,frame=2)
ljcd<-dnaRanges(ljc,dna_small)
ljcdw<-extractByGeneName(ljcd, geneNames="WASH7P", src=uc)
# F) For caRanges
ljca<-translate(ljcd)
ljcaw<-extractByGeneName(ljca, geneNames="WASH7P", src=uc)
# G) For gapSites
lrj<-lRJunc(ga,lfeatlen=6,rfeatlen=6,strand='+')
lrjw<-extractByGeneName(lrj, geneNames="WASH7P", src=uc)
```

---

extractRange

*extractRange: Extract subset from object where records lie in given range.*

---

**Description**

Searches in object for data which lie inside the given range and returns an object of same type containing extracted data.

**Usage**

```
extractRange(object, seqid, start, end)
```

**Arguments**

object	gapSites or cRanges (or derived). Object inside which the data is searched for.
seqid	character. Reference sequence identifier.
start	numeric. Start position of given range.
end	numeric. End position of given range.

**Value**

Same type as object

**Author(s)**

Wolfgang Kaisers

**Examples**

```
# A) Read gapSites
bam<-system.file("extdata","rna_fem.bam",package="spliceSites")
reader<-bamReader(bam,idx=TRUE)
ga<-alignGapList(reader)
bamClose(reader)
# B) Load refGenome
ucf<-system.file("extdata","uc_small.RData",package="spliceSites")
uc<-loadGenome(ucf)
# C) For gapSites
extractRange(ga,seqid="chr1",start=14000,end=30000)
# D) For cRanges
lj<-lJunc(ga,featlen=3,gaplen=6,strand='+')
extractRange(lj,seqid="chr1",start=14000,end=30000)
```

---

gapSites

*Creating 'gapSites' and 'dnaGapSites' objects.*

---

**Description**

gapSites creates objects of class gapSites from scratch. dnaGapSites creates objects of class dnaGapSites from gapSites objects.

**Usage**

```
gapSites(seqid=factor(),lstart=integer(),lend=integer(),
         rstart=integer(),rend=integer(),gaplen,strand,
         nr_aligns=1,nAligns=sum(nr_aligns),
         nAlignGaps=sum(nr_aligns),nProbes=1)
```

**Arguments**

seqid	Character. Identifies reference sequence.
lstart	Coordinates for start of left range.
lend	Coordinates for end of left range. Usually exon-intron boundary.
rstart	Coordinates for start of right range. Usually exon-intron boundary.
rend	Coordinates for end of right range.
gaplen	Length of enclosed gap. Should equal rstart-lend-1.
strand	+ or - or * (for unknown). Default: '*'.
nr_aligns	Number of gapped aligns which have the same exon-intron boundaries (lend and rstart)
nAligns	Total number of aligns for probeset.
nAlignGaps	Total number of gapped aligns for probeset.
nProbes	Numeric. Number of probes in which this gapped position is present.

**Details**

The intended way to create a gapSites object is to use the alignGapList function which in turn calls the (rBamTools) bamGapList function. When a BAM file almost exclusively contains gapped aligns which sometimes are multiply gapped, possibly the 'nAlignGaps' value is greater than the 'nAligns'. When reading BAM files which contain the complete data of an alignment, usually the 'nAlignGaps' value is about 1/3 of the 'nAligns' value.

**Value**

An object of class 'gapSites'.

**Author(s)**

Wolfgang Kaisers

**Examples**

```
# A) Construct source data from scratch
seqid<-c("chr1","chr1","chr2","chr2","chr2")
lstart<-c(900, 1900,900 ,900, 1900)
lend <-c(1000,2000,1000,1000,2000)
rstart<-c(1100,2100,1100,1200,2100)
rend <-c(1200,2200,1200,1300,2200)
nr_aligns<-c(10,20,30,40,10)

# B) Construct gapSites object
ga<-gapSites(seqid,lstart,lend,rstart,rend,nr_aligns=nr_aligns)
ga

# C) Use gapSites accessors
seqid(ga)
lend(ga)
```

```

rstart(ga)
strand(ga)
gptm(ga)
rpmg(ga)
nAligns(ga)
nAlignGaps(ga)

# D) Create
bam<-system.file("extdata", "rna_fem.bam", package="spliceSites")
reader<-bamReader(bam,idx=TRUE)
ga<-alignGapList(reader)
ga
dnafile<-system.file("extdata","dna_small.RData",package="spliceSites")
load(dnafile)
dga<-dnaGapSites(ga,dna_small)

```

---

gapSites-class	<i>Class "gapSites": Container for tabulated alignment gap positions on RNA-seq data.</i>
----------------	---

---

## Description

Contains tabulated data on alignment gaps on RNA - seq data. `getalignGaps(reader,seqid)` reads gapped alignments for the specified seqid from a BAM file (via CRAN rbamtools) into an object of class "gapSites".

## Objects from the Class

Objects can be created by calls of the form `alignGapList(reader)`.

## Slots

**nAligns:** Object of class "numeric" Total number of aligns in alignment.

**nAlignGaps:** Object of class "numeric" Total number of gapped aligns in alignment.

**dt:** Object of class "data.frame" Table containing basic data for object.

**annotation:** Object of class "dataFrameOrNULL" Optional data.frame containing annotation data.

**profile:** dataFrameOrNULL Optional. Contains probe information (Name of BAM-file, group affiliation, number of sites).

## Methods

**as.data.frame** signature(x = "gapSites"): Returns copy of contained data.frame.

**c** signature(x = "gapSites"): Specialisation of generic combine function.

**dim** signature(x = "gapSites"): Specialisation of generic dim function.

**dnaGapSites** signature(x = "gapSites", dnaset="DNAStringSet"): Create dnaGapSites object by adding DNA sequences.

- getAnnStrand** signature(x): Return strand vector based on annotation content.
- getProfile** signature(x): Return profile table (data.frame) which contains BAM-file names, group affiliation and number of Sites.
- gptm** signature(x = "gapSites"): Reading accessor for gptm values.
- head** signature(x = "gapSites"): Specialisation of generic head function.
- lRCodons** signature(x = "gapSites"): Returns gapSites object where lstart and rend positions are truncated toward the next smaller full codon position (used for preparation of translation to amino acid sequence)
- lJunc** signature(x = "gapSites", featlen="numeric", gaplen="numeric", keepStrand="logical" (F), featlen: Number nucleotides of feature (=exon). gaplen: Number of nucleotides of gap (=intron). keepStrand: Values for strand are copied from argument, otherwise all positions are marked as "+". unique: Multiple identical positions (arising from alternative splice sites on the right side) are collapsed to one line (number of sites is counted in "mult"). Position: 0-based position of last exon nucleotide in DNA sequence.
- lRJunc** signature(x = "gapSites", lfeatlen="numeric", rfeatlen="numeric", "strand"): Returns gapSites object where positions are shifted so that given feature length's are present for lstart and rend positions (used as preparatory steps for obtaining sensible seq - logo's on exonic junction regions).
- addGeneAligns** signature(object="gapSites"): Adds number of alignments per gene as new column to alignment gap position table. Annotation tables must be present. Otherwise an error occurs.
- merge** signature(x = "gapSites", y = "ANY"): Specialisation of generic merge (data.frame) function.
- nAligns** signature(object = "gapSites"): Reading accessor for nAligns value.
- nAlignGaps** signature(object = "gapSites"): Reading accessor for nAlignGaps value.
- rpmg** signature(x = "gapSites"): Reading accessor for rpmg values.
- show** signature(object = "gapSites"): Specialisation of generic show function.
- sortTable** signature(x="gapSites"): Sorts all contained tables by seqid, lend and rstart.
- write.annDNA.tables** signature(x="gapSites", dnaset="DNAStrngSet", filename="character"), Writes csv file with gap-positions, annotations and dna-sequence.

**Author(s)**

Wolfgang Kaisers

**See Also**

dnaGapSites

**Examples**

```
bam<-character(2)
bam[1]<-system.file("extdata", "rna_fem.bam", package="spliceSites")
bam[2]<-system.file("extdata", "rna_mal.bam", package="spliceSites")
reader<-bamReader(bam[1], idx=TRUE)
```

```
agl<-alignGapList(reader)
agl
bamClose(reader)

mbs<-readMergedBamGaps(bam)
mbs
getProfile(mbs)
```

---

getGapSites

*Read* gapSites

---

### Description

getGapSites and alignGapList read gap-site data from single BAM-files (given as bamReader) and return a gapSites object. getGapSites reads data for one seqid (given as 1-based numeric value). alignGapList reads the whole BAM-file. The functions test for opened reader and initialized index.

### Usage

```
getGapSites(reader,seqid,startid=1)
```

### Arguments

reader	bamReader (rbamtools). An opened instance of bamReader with initialized index.
seqid	Numeric. 1-based index of reference sequence for which gap-sites are to be read.
startid	Numeric. Default: 1. Determines start value for id column from which the values are ascending enumerated. startid greater than 1 allow to produce unique values over multiple BAM-files.

### Details

getGapSites internally calls rbamtools::gapList. alignGapList internally calls rbamtools::bamGapList. 'nProbes' values are set to 1.

### Value

gapSites

### Author(s)

Wolfgang Kaisers

**Examples**

```

bam<-system.file("extdata", "rna_fem.bam", package="spliceSites")
reader<-bamReader(bam,idx=TRUE)
gal<-getGapSites(reader,1,startid=10)
gal
gal<-alignGapList(reader)
gal

```

---

hbond-class

*Class "hbond"*

---

**Description**

Provides methods and data for calculation of HBond 5' splice-site scores. HBond scores provide a measure for the capability of a 5' splice-site to form H-bonds with the U1 snRNA. The function requires at least 3 exon nucleotides and 8 intron nucleotides. The hbond function takes a vector DNA sequences and a vector of position (pos) values. The position values represent the 1-based position of the last exon nucleotide. Therefore all position values must be  $\geq 3$  and the sequence length must be  $\geq \text{pos} + 8$ .

**Details**

The first two intron nucleotides must be 'GT' otherwise returned value is 0. All other sequence characters must be in "ATCG" (capitalization does not matter). When any other character (such as N) is found, the function also returns 0.

**Creation of hbond objects**

Objects can be created by `load.hbond()`.

**Slots**

**ev:** Object of class "environment" Contains external score data.

**basedir:** Object of class "character" Directory from which external data is restored.

**Methods**

**basedir** signature(x = "hbond"): Returns basedir value.

**basedir<-** signature(x = "hbond",value="character"): Sets basedir value.

**hbond** signature(x = "hbond",seq="character",pos="integer"): Calculates score5 value for seq at given position.

**Author(s)**

Wolfgang Kaisers

**References**

[http://www.uni-duesseldorf.de/rna/html/hbond\\_score.php](http://www.uni-duesseldorf.de/rna/html/hbond_score.php)

**Examples**

```
hb<-load.hbond()
seq<-c("CAGGTGAGTTC", "ATGCTGGAGAA", "AGGGTGCGGGC", "AAGGTAACGTC", "AAGGTGAGTTC")
hbond(hb, seq, 3)
```

---

head-methods	head <i>Return first lines of contained data.frame.</i>
--------------	---

---

**Description**

Methods for function head.

**Methods**

signature(x = "cRanges") Method for 'cRanges'.

signature(x = "aaGapSites") Method for 'aaGapSites'.

signature(x = "cdRanges") Method for 'cdRanges'.

signature(x = "cRanges") Method for 'cRanges'.

signature(x = "dnaGapSites") Method for 'dnaGapSites'.

signature(x = "gapSites") Method for 'gapSites'.

---

initialize-methods	initialize <i>Initializing objects.</i>
--------------------	---

---

**Description**

Methods for function initialize

**Methods**

signature(.Object = "cdRanges") Method for 'cdRanges'.

signature(.Object = "cRanges") Method for 'cRanges'.

signature(.Object = "keyProfiler") Method for 'keyProfiler'.

signature(.Object = "SpliceCountSet") Method for 'SpliceCountSet'.

---

keyProfiler-class      *Class "keyProfiler"*

---

### Description

Internal class that counts occurrence of profile factors (e.g. gender male and female) successively for added key-tables. The columns of the key-tables define the groups (e.g. genomic positions: seqid, start, end) for each all profile factors are counted.

### Objects from the Class

Objects can be created by calls of the form `new("annAligns", ...)`.

### Slots

**ev:** Environment: contains the main data of each object. The environment contains the data.frames 'dtb' (key-tabled profiles) and 'prof' (profiles: a table that contains the profile definition for each added key-table) as well as 'groupExpr', an unevaluated Expression which does the data.frame-grouping after addition of a new key-table.

**unique:** Logical: When true, there can be maximal one table added for each indexed profile

**counted:** Logical: Stores the information which profile already has been counted. Is only used when 'unique' is 'TRUE'.

**useValues:** Logical: When TRUE, the object tables the values given together with each key-table, otherwise the profiles are simply counted.

### Methods

**addKeyTable** signature(x = "keyProfiler", keyTable="data.frame", index="numeric", values="numeric"): Adds keyed data to key-table and counts values according to profile (which is defined by index via profile table).

**getKeyTable** signature(x = "keyProfiler"): Returns key-table.

**appendKeyTable** signature(x = "keyProfiler", keytable="data.frame", prefix="character", valFactor="numeric"): Appends internal key-table to keytable-argument. A prefix can be added to column-names. A given valFactor is multiplied with the counted values. A given rateFactor causes counted values to be converted into rates (i.e. divided by column-sums and multiplied with rateFactor value. Values are rounded when a digits argument is provided.)

### Author(s)

Wolfgang Kaisers

**Examples**

```
# Loads profile, position data (key) and aggregated values (ku) data.frames
load(system.file("extdata", "key.RData", package="spliceSites"))
# Group positions
kpc<-new("keyProfiler",keyTable=key1[,c("seqid","lend","rstart")],prof=prof)
addKeyTable(kpc,keyTable=key2[,c("seqid","lend","rstart")],
            index=2,values=key2$nAligns)
addKeyTable(kpc,keyTable=key3[,c("seqid","lend","rstart")],
            index=4,values=key3$nAligns)
cp<-appendKeyTable(kpc,ku,prefix="c.")
```

lrcodons

*lrcodon methods***Description**

The `lrcodon` function works on `gapSites` objects. `gapSites` manage data on align-gaps which represent data on RNA splice sites. On the contained ranges the function can have two effects: an upstream frame-shift of 0 to 2 positions and a downstream trim to full codons (i.e.  $(\text{end-start}+1)\%3==0$ ). The strand argument controls direction of effects: '+' strand mode means left frame-shift and right truncation. '-' strand mode means right frame-shift and left truncation.

**Usage**

```
lrcodons(x, frame=1L, strand="+")
```

**Arguments**

<code>x</code>	<code>gapSites</code> . Object in which codon positions are calculated
<code>frame</code>	Numeric. Default is 1. Accepted values are 1,2 or 3. The value causes a frame-shift of size $(\text{frame}-1)$ .
<code>strand</code>	Character or numeric. Default is '+' which is equivalent to 0. Any other value will be interpreted as '-' which is equivalent to 1.

**Details**

The function causes an upstream frameshift and a downstream truncation. `gapSites` objects contain data on gap aligns which represent a related pair of exon-intron boundaries. The returned object is of the same class as the input. Supplemented DNA sequence `gapSites` objects will omit introns and will represent the 'spliced' DNA around the splice site. `lrcodon` function is intended to shift coordinates, so that the resulting DNA-sequence can readily be translated in a putative amino-acid sequence which contains the splice-site.

**Author(s)**

Wolfgang Kaisers

## Examples

```
# A) Create gapSites object
bam<-system.file("extdata","rna_fem.bam",package="spliceSites")
reader<-bamReader(bam,idx=TRUE)
ga<-alignGapList(reader)
bamClose(reader)

# B) lr-Junctions for '+' -strand
lrj<-lrJunc(ga,lfeatlen=6,rfeatlen=6,strand='+')
lr1<-lrCodons(lrj,frame=1)
lr2<-lrCodons(lrj,frame=2)
lr3<-lrCodons(lrj,frame=3)
lr<-c(lr1,lr2,lr3)

# C) lr-Junctions for '-' -strand
lrj<-lrJunc(ga,lfeatlen=6,rfeatlen=6,strand='-')
lr1<-lrCodons(lrj,frame=1)
lr2<-lrCodons(lrj,frame=2)
lr3<-lrCodons(lrj,frame=3)
lr<-c(lr1,lr2,lr3)
```

---

maxEnt-class

*Class "maxEnt"*

---

## Description

Provides methods for calculation of Splice-site scores. Both functions (score5 and score3) are intended to work on the '+' strand. score5 scores the 5' side (i.e. the splice donor, left) and the score3 scores the 3' side (i.e. the splice acceptor, right).

## Creation of maxEnt objects

Objects can be created by `load.maxEnt()`.

## Slots

**ev:** Object of class "environment" Contains external score data.

**basedir:** Object of class "character" Directory from which external data is restored.

## Methods

**basedir** signature(x = "maxEnt"): Returns basedir value.

**basedir<-** signature(x = "maxEnt", value="character"): Sets basedir value.

**score5** signature(x = "maxEnt", seq="character", pos="integer"): Calculates score5 value for seq at given position.

**scoreSeq5** signature(x="maxEnt", seq="character", frame="integer"): Calculates score5 values for a single sequence and a series of positions (frame).

**score3** signature(x = "maxEnt", seq="character", pos="integer", which="character"): Calculates score3 value for seq at given position. Accepted values for which are: "ent", "wmm" and "emm".

**scoreSeq3** signature(x = "maxEnt", seq="character", frame="integer", which="character"): Calculates score3 values for a single sequence and a series of positions (frame). Accepted values for which are: "ent", "wmm" and "emm".

### Author(s)

Wolfgang Kaisers

### Examples

```
mes<-load.maxEnt()
score5(mes, "CCGGTAAGAA", 4) # 9.844127
score3(mes, "CTCTACTACTATCTATCTAGATC", pos=20) # 6.706947

# scoreSeq functions
sq5<-scoreSeq5(mes, seq="ACGGTAAGTCAGGTAAGT")
sq3<-scoreSeq3(mes, seq="TTTTTTTTCTCACTTTTAGAGACTTCATTCTTCTCAAATAGGTT")
```

---

merge-methods

merge *Merging two objects into one.*

---

### Description

Methods for function merge

### Methods

signature(x = "gapSites", y = "ANY") Method for 'gapSites'.

---

plotGeneAlignDepth

*plotGeneAlignDepth: Plots of read alignment depth for genetic regions*

---

### Description

The function takes a bamReader and a refGenome object together with a gene name and an optional transcript name and plots the read alignment depth for the region of the gene in the opened BAM file. When transcript data is present, the exonic ranges are added as rectangles on a chromosomal line.

**Usage**

```
plotGeneAlignDepth(reader, genome,
                   gene=NULL, transcript=NULL,
                   log="y", cex.main=2,
                   col="grey50", fill="grey90", grid=TRUE,
                   box.col="grey20", box.border="grey80")
```

**Arguments**

reader	bamReader (rbamtools). Must be opened and have initialized index.
genome	refGenome. Object which contains genomic annotation data.
gene	character. Name of one single gene.
transcript	character (optional). Name of one single transcript.
log	character. Name of one single gene.
cex.main	numeric. Determines size of main title.
col	color. A color for align depth line.
fill	color. A color for the interior of align depth area.
grid	logical. When TRUE, a grid is drawn.
box.col	color. A color for the interior of exon rectangles.
box.border	color. A color for the border of exon rectangles.

**Details**

The function checks for opened bamReader and initialized index. When transcript name is given, the function will plot the positions of the transcript beneath the alignment depth.

**Author(s)**

Wolfgang Kaisers

**Examples**

```
# Open bamReader
bam <- system.file("extdata", "rna_fem.bam", package="spliceSites")
reader <- bamReader(bam, idx=TRUE)
# Load annotation data
ucf <- system.file("extdata", "uc_small.RData", package="spliceSites")
uc <- loadGenome(ucf)
plotGeneAlignDepth(reader, uc, gene="WASH7P", transcript="uc001aac.4")
```

---

rangeByGeneName	<i>Reads a bamRange object for a given bamReader, refGenome and gene name.</i>
-----------------	--

---

### Description

Locates gene in genome via refGenome and reads a bamRange from the determined region.

### Usage

```
rangeByGeneName(reader, genome, gene, complex=TRUE)
```

### Arguments

reader	Object of class (rbamtools) bamReader. The reader must pass isOpen and index.initialized test.
genome	Object of class (refgenome) refGenome.
gene	Single gene name (character)
complex	Logical. Passed to 'bamRange' function. When TRUE, only aligns with nCigar>1 are counted.

### Value

bamRange

### Author(s)

Wolfgang Kaisers

### Examples

```
bam<-system.file("extdata","rna_fem.bam",package="spliceSites")
reader<-bamReader(bam,idx=TRUE)
ucf<-system.file("extdata","uc_small.RData",package="spliceSites")
uc<-loadGenome(ucf)
range<-rangeByGeneName(reader,uc,"WASH7P")
size(range)
```

---

readCuffGeneFpkm      *Reads FPKM values into ExpressionSet.*

---

### Description

Opens fpkm\_tracking files and collects FPKM values into ExpressionSet. The function is intended to work with genes.fpkm\_tracking files. In order to get unique gene identifier, the contained values are grouped and for each gene the maximum FPKM values is selected. There should only be a few hundred multiple occurring genes and the maximum value should give a (slight) underestimation of the real value.

### Usage

```
readCuffGeneFpkm(cuff, phenoData, summ="max")
```

### Arguments

cuff	character: Vector of cufflinks files
phenoData	AnnotatedDataFrame: Requirement for construction of an ExpressionSet
summ	character: Must be either 'max' or 'sum'. A handful of tracking id's occur multiple times due to multiple transcripts which partially are non-overlapping. The summ (summarize) Argument determines the way the multiplots are handled.

### Value

ExpressionSet

### Author(s)

Wolfgang Kaisers

### Examples

```
n<-10
cuff <- system.file("extdata", "cuff_files",
  paste(1:n, "genes", "fpkm_tracking", sep="."), package="spliceSites")

## Create Pheno - data
gr <- system.file("extdata", "cuff_files", "groups.csv", package="spliceSites")
groups <- read.table(gr, sep="\t", header=TRUE)
meta <- data.frame(labelDescription=c("gender", "age-group", "location"),
  row.names=c("gen", "agg", "loc"))
phenoData <- new("AnnotatedDataFrame", data=groups, varMetadata=meta)

## Read ExpressionSet
exset <- readCuffGeneFpkm(cuff, phenoData)
```

---

readExpSet	<i>Reads align number or gptm or rpmg value from all given BAM-files and all identified align gaps into ExpressionSet.</i>
------------	--

---

### Description

Opens multiple BAM-files and reads aligns for selected gene for each file. Number of alignes is counted.

### Usage

```
readExpSet(bam, idx, val="nAligns", phenoData, expData)
```

### Arguments

bam	Vector of BAM-files
idx	Vector of index files (optional)
val	"gptm", "rpmg" or "nAligns". Value type which is written to ExpressionSet matrix (nAligns = read count).
phenoData	AnnotatedDataFrame. Each BAM-file must correspond to one identifier.
expData	MIAME. Optional. Experiment data which can be added to ExpressionSet

### Value

ExpressionSet

### Author(s)

Wolfgang Kaisers

### Examples

```
# A) Names of BAM-files
bam <- character(2)
bam[1] <- system.file("extdata", "rna_fem.bam", package="spliceSites")
bam[2] <- system.file("extdata", "rna_mal.bam", package="spliceSites")

# B) Experiment Profile
prof <- data.frame(gender=c("f", "m"))
meta <- data.frame(labelDescription=names(prof), row.names=names(prof))
pd <- new("AnnotatedDataFrame", data=prof, varMetadata=meta)

# C) Read ExpressionSet
es <- readExpSet(bam, phenoData=pd)

# D) Annotate ExpressionSet
ucf <- system.file("extdata", "uc_small_junc.RData", package="spliceSites")
juc <- loadGenome(ucf)
```

```
ann <- annotate(es, juc)
phenoData(es) <- ann
```

---

readMergedBamGaps      *Reads an object of type gapSites using a vector of BAM file names.*

---

### Description

The function takes a vector of BAM-file names and corresponding BAM-index file names. For each given filename, the BAM-file will be opened. The functions uses the bamGapList function (rbamtools) to obtain a data.frame from an bamReader. Values for 'gptm' and 'rpmg' are added. Both are rounded to the number of given digits. The function tests for open connection to BAM-file and for initialized index.

### Usage

```
readMergedBamGaps(infiles,idxInfiles=paste(infiles,".bai",sep=""),digits=3)
```

### Arguments

infiles	character. Name of BAM-files to be opened.
idxInfiles	character. Name of corresponding BAM-index files. Default: paste(infiles,".bai",sep="")
digits	numeric. gptm and rpmg values will be rounded to the number of decimal places given.

### Value

gapSites

### Author(s)

Wolfgang Kaisers

### Examples

```
bam<-character(2)
bam[1]<-system.file("extdata","rna_fem.bam",package="spliceSites")
bam[2]<-system.file("extdata","rna_mal.bam",package="spliceSites")
mbg<-readMergedBamGaps(bam)
```

---

readTabledBamGaps      *readTabledBamGaps function*

---

## Description

readTabledBamGaps

## Usage

```
readTabledBamGaps(infiles, idxInfiles=paste(infiles, ".bai", sep=""), prof, rpmg=TRUE)
```

## Arguments

infiles	character. Names of BAM-files.
idxInfiles	character. Names of BAM-index files. When given index file is not found, the function attempts to create a BAM-index file with the depicted name.
prof	data.frame. Contains group affiliations for each BAM-file. Each column describes an entity by which values are grouped. The row-number in prof must be equal to the number of given BAM-files. The order of BAM infiles and prof defines the group classification for each BAM file. All prof columns must be factors.
rpmg	logical. When TRUE, there will be group specific rpmg align-rates be added to the result table

## Details

The function reads gap-align data from all given BAM-files. For each factor level, the number of probes and aligns are counted. When gptm=TRUE also the gptm values are written for each group. The result table contains for each prof factor level 2 (or 3) extra columns.

## Value

gapSites

## Author(s)

Wolfgang Kaisers

## Examples

```
bam<-character(2)
bam[1]<-system.file("extdata", "rna_fem.bam", package="spliceSites")
bam[2]<-system.file("extdata", "rna_mal.bam", package="spliceSites")
prof<-data.frame(gender=c("f", "m"))
rtbg<-readTabledBamGaps(bam, prof=prof, rpmg=TRUE)
rtbg
getProfile(rtbg)
```

---

seqlogo	<i>seqlogo: Plotting sequence logo for 'cdRanges' and 'dnaGapSites' objects.</i>
---------	--

---

## Description

The function produces a sequence logo plot based on the contained sequences.

## Usage

```
seqlogo(x, strand="+", useStrand=TRUE, ...)
```

## Arguments

x	cdRanges or dnaGapSites Object.
strand	Character. Determines the subset for which the seqlogo is plotted. This option is only used when useStrand is given as 'TRUE'.
useStrand	Logical. Determines whether the given strand information is used. For useStrand=FALSE the plot is made up from all contained sequences.
...	(Currently unused)

## Details

The function fails with an error message when the dataset does not contain any records with the given strand (except useStrand=FALSE).

## Value

None

## Author(s)

Wolfgang Kaisers

## Examples

```
bam<-system.file("extdata","rna_fem.bam",package="spliceSites")
reader<-bamReader(bam,idx=TRUE)
ga<-alignGapList(reader)
bamClose(reader)
lj<-lJunc(ga,featlen=6,gaplen=6,strand='+')
dnafile<-system.file("extdata","dna_small.RData",package="spliceSites")
load(dnafile)
ljd<-dnaRanges(lj,dna_small)
seqlogo(ljd)
```

---

silic_tryp	<i>silic_tryp function</i>
------------	----------------------------

---

**Description**

silic\_tryp performs silicon trypsination and returns the fragments to which the position coordinate points. The position value is corrected so that it afterwards points to the same amino-acid as before.

**Usage**

```
silic_tryp(seq,pos,id)
```

**Arguments**

seq	Character. Amino-acid sequences which are to be truncated.
pos	Numeric. Points to an amino-acid inside the sequence.
id	Numeric. An identifier which is copied to the result table.

**Details**

The routine implements the "Keil"-rule, where sites are described by the regex "[RK](?!P)". The cut position is between [RK] and the following character. The sequence fragment which contains the exon-intron boundary (depicted by position) is returned. Dependent numeric values are recalculated.

**Value**

data.frame

**Author(s)**

Wolfgang Kaisers

**Examples**

```
silic_tryp(seq="AXKUEMRFG",pos=4)
```

---

sortTable-methods	<i>Sorting contained data with sortTable.</i>
-------------------	---

---

**Description**

Sorting tables by key columns.

**Methods**

signature(x = "cRanges") Method for 'cRanges'. Key columns: seqid, start, end  
signature(x = "gapSites") Method for 'gapSites'. Key columns: seqid, lend, rstart

---

```
SpliceCountSet-class  Class "SpliceCountSet"
```

---

**Description**

Directly inherits from ExpressionSet

**Objects from the Class**

Objects can be created by calls of the form `new("SpliceCountSet", ...)`.

**Author(s)**

Wolfgang Kaisers

**Examples**

```
# scs<-new("SpliceCountSet")
```

---

```
trim                trim and resize methods: trim_left, trim_right, resize_left, resize_right
```

---

**Description**

The trim and resize functions change number of nucleotides contained in align-gap features (exonic). Trim functions cut feature sizes down to `maxlen`. Resize functions reset all sizes to a fixed value. The functions operate directly on the passed objects. There is no return value.

**Usage**

```
trim_left(x,maxlen)
```

**Arguments**

<code>x</code>	gapSites. Object from which the lJunc values are calculated.
<code>maxlen</code>	Numeric. Maximum number of nucleotides on feature (exon) side of boundary.

**Value**

None.

**Author(s)**

Wolfgang Kaisers

**Examples**

```

# A) Create gapSites object
bam<-system.file("extdata","rna_fem.bam",package="spliceSites")
reader<-bamReader(bam[1],idx=TRUE)
ga<-alignGapList(reader)
bamClose(reader)
ga
# B) Trim
trim_left(ga,3)
trim_right(ga,2)
ga
# C) Resize
resize_left(ga,5)
resize_right(ga,6)
ga

```

---

truncateSeq

*truncateSeq method*

---

**Description**

truncateSeqs amino acid sequences at positions depicted by '\*' (stop-codon).

**Usage**

```
truncateSeq(x, rme=TRUE, trunc=42L)
```

**Arguments**

x	caRanges. Object in which amino-acid sequences are to be truncated.
rme	Logical. Default is TRUE. When TRUE, sites with resulting empty sequence (i.e. stop-codon upstream of the splice position) are removed from dataset.
trunc	Integer. ASCII code for character at which truncation should occur. Default value is 42='*' (stop-codon).

**Details**

The function truncateSeqs the contained amino acid sequences. When the stop-codon is found on the left side of position, the function returns an empty sequence for that site. The position values for these records are also set to 0.

**Value**

Object of same class as input.

**Author(s)**

Wolfgang Kaisers

**Examples**

```
# A) Read gap-sites from BAM-file
bam<-system.file("extdata","rna_fem.bam",package="spliceSites")
reader<-bamReader(bam,idx=TRUE)
ga<-alignGapList(reader)
bamClose(reader)
# B) Load DNA sequence
dnafile<-system.file("extdata","dna_small.RData",package="spliceSites")
load(dnafile)
ucf<-system.file("extdata","uc_small.RData",package="spliceSites")
uc<-loadGenome(ucf)
# C) Calculate codon frame data and add DNA
lj<-lJunc(ga,featlen=21,gaplen=21,strand='+')
ljc<-lCodons(lj,frame=1,keepStrand=TRUE)
cdr<-dnaRanges(ljc,dna_small)
# D) Translate DNA to amino acid and truncate
ar<-translate(cdr)
tra<-truncateSeq(ar)
```

truncate\_seq

*truncate\_seq function***Description**

truncateSeqs amino acid sequences at positions depicted by '\*' (stop-codon).

**Usage**

```
truncate_seq(seq,pos,id,rme=TRUE,trunc=42L)
```

**Arguments**

seq	Character. Amino-acid sequences which are to be truncated.
pos	Numeric. Points to an amino-acid inside the sequence.
id	Numeric. An identifier which is copied to the result table.
rme	Logical. Empty sequences are removed when set to TRUE.
trunc	Integer. ASCII code for character at which truncation should occur. Default value is 42='*' (stop-codon).

**Details**

The function truncateSeqs the contained amino acid sequences. When the stop-codon is found on the left side of position, the function returns an empty sequence for that site. The position values for these records are also set to 0.

**Value**

data.frame

**Author(s)**

Wolfgang Kaisers

**Examples**

```
truncate_seq(seq="ARPX*QR", pos=3)
```

---

trypsinCleave	<i>trypsinCleave method</i>
---------------	-----------------------------

---

**Description**

trypsinCleave cleaves amino acid sequences and returns the fragment which contains the position described by position entry in data.frame.

**Usage**

```
trypsinCleave(x, minLen=5, ...)
```

**Arguments**

x	caRanges (aaGapSites). Object in which amino-acid sequences are to be truncated.
minLen	Numeric. Default is 5. Data sets where the remaining sequence fragment is shorter than minLen are excluded.
...	Additional arguments which may be passed to the routine (currently unused).

**Details**

The routine implements the "Keil"-rule, where sites are described by the regex "[RK](?!P)". The cut position is between [RK] and the following character. The sequence fragment which contains the exon-intron boundary (depicted by position) is returned. Dependent numeric values are recalculated. The returned sequence ends on "[RK]" unless the returned fragment is a sequence suffix.

**Value**

Same class as given object.

**Author(s)**

Wolfgang Kaisers

**Examples**

```

bam<-system.file("extdata","rna_fem.bam",package="spliceSites")
reader<-bamReader(bam,idx=TRUE)
ga<-alignGapList(reader)
bamClose(reader)
ga
lj<-lJunc(ga,featlen=21,gaplen=21,strand='+')
ljc<-lCodons(lj,frame=1,keepStrand=TRUE)
dnafile<-system.file("extdata","dna_small.RData",package="spliceSites")
load(dnafile)
cdr<-dnaRanges(ljc,dna_small)
ar<-translate(cdr)
tra<-truncateSeq(ar)
tyc<-trypsinCleave(tra)

```

---

uniqueJuncAnn

*uniqueJuncAnn method for ExpressionSet*

---

**Description**

uniqueJuncAnns adds annotation data to ExpressionSet and removes not-matching sites.

**Usage**

```
uniqueJuncAnn(object,junc,ann=TRUE,...)
```

**Arguments**

object	ExpressionSet. Object containing gap-site expression data.
junc	refJunctions. Object containing splice-junction sites.
ann	logical. Default: TRUE. When TRUE the unannotated sites are removed, otherwise the annotated sites are removed.
...	Unused.

**Value**

ExpressionSet

**Author(s)**

Wolfgang Kaisers

**Examples**

```

# A) Names of BAM-files
bam<-character(2)
bam[1]<-system.file("extdata","rna_fem.bam",package="spliceSites")
bam[2]<-system.file("extdata","rna_mal.bam",package="spliceSites")

# B) Experiment Profile
prof<-data.frame(gender=c("f","m"))
meta<-data.frame(labelDescription=names(prof),row.names=names(prof))
pd<-new("AnnotatedDataFrame",data=prof,varMetadata=meta)

# C) Read ExpressionSet
es<-readExpSet(bam,phenoData=pd)

# D) Annotate ExpressionSet
ucf<-system.file("extdata","uc_small.RData",package="spliceSites")
uc<-loadGenome(ucf)
ucj<-getSpliceTable(uc)

# E) Extract unique annotated junction sites.
uja<-uniqueJuncAnn(es,ucj)

```

---

write.files

*write.files*

---

**Description**

Writes table data and sequence in separate files.

**Usage**

```
write.files(x, path, filename,...)
```

**Arguments**

x	caRanges or aaGapSites object for which data is written.
path	Path for writing files.
filename	Basic filename to which suffixes are added.
...	Other arguments passed to "write.table".

**Details**

There are two files written: A text file with tabulated values from data.frame (separated by ";") and a fasta file which contains the stored dna sequence.

**Value**

None.

**Note**

The function tries to create directory 'path' when it does not exist.

**Author(s)**

Wolfgang Kaisers

**Examples**

```
# A) Read gap-sites from BAM-files
bam<-system.file("extdata","rna_fem.bam",package="spliceSites")
reader<-bamReader(bam,idx=TRUE)
ga<-alignGapList(reader)
bamClose(reader)
# B) Load DNA sequence
dnafile<-system.file("extdata","dna_small.RData",package="spliceSites")
load(dnafile)
# C) Add DNA sequence
lj<-lJunc(ga,featlen=21,gaplen=21,strand='+')
ljc<-lCodons(lj,frame=1,keepStrand=TRUE)
cdr<-dnaRanges(ljc,dna_small)
# D) Translate DNA to amino-acid
ar<-translate(cdr)
# E) Write "ar.csv" and "ar.fa"
# write.files(ar, ".", "ar")
```

---

xCodons

*xCodon methods*

---

**Description**

The xCodon functions work on cRanges objects. On the contained ranges the function can have two effects: an upstream frame-shift of 0 to 2 positions and a downstream trim to full codons (i.e. (end-start+1)%3==0). The lCodon function acts in '+' strand mode (left frame-shift, right truncation) and the rCodon function acts in '-' strand mode (right frame-shift, left truncation).

**Usage**

```
lCodons(x, frame=1, keepStrand=TRUE)
```

**Arguments**

x	cRanges. Object in which codon positions are calculated
frame	Numeric. Default is 1. Accepted values are 1,2 or 3. The value causes a frame-shift of size (frame-1).
keepStrand	Logical. Default is TRUE. When FALSE, lCodons overwrites strand entries by '+' and rCodons overwrites strand entries by '-'.

## Details

The function causes an upstream frameshift and a downstream truncation. lCodon works with '+'-strand view (left-to-right) and rCodon works with '-'-strand view (right to left). The underlying rationale is: The cRanges object contains ranges around exon-intron boundaries. The boundary itself is marked by the position value. The functions calculate genomic ranges which can be supplemented by the reference DNA-sequence which then can readily be translated into amino-acid sequences. The different values for frame and keepStrand are used to produce all six putative amino-acid sequences for this exon-intron boundary.

## Author(s)

Wolfgang Kaisers

## Examples

```
bam<-system.file("extdata","rna_fem.bam",package="spliceSites")
reader<-bamReader(bam,idx=TRUE)
ga<-alignGapList(reader)
bamClose(reader)
dnafile<-system.file("extdata","dna_small.RData",package="spliceSites")
load(dnafile)
ucf<-system.file("extdata","uc_small.RData",package="spliceSites")
uc<-loadGenome(ucf)

lj<-lJunc(ga,featlen=21,gaplen=21,strand='+')
ljc<-lCodons(lj,frame=1,keepStrand=TRUE)
rj<-rJunc(ga,featlen=21,gaplen=21,strand='-')
rjc<-rCodons(rj,frame=1,keepStrand=TRUE)
```

---

xJunc

*xJunc methods: lJunc, rJunc, lrJunc*

---

## Description

The term 'xJunc' envelopes three functions: lJunc, rJunc and lrJunc. All three functions take a gapSites object and return ranges which are restricted around align-gap (exon-intron) boundaries. The functions lJunc and rJunc return cRanges objects, the lrJunc function returns a gapSites object.

## Usage

```
lJunc(x,featlen,gaplen,unique=FALSE,strand,...)
```

## Arguments

x	gapSites. Object from which the lJunc values are calculated.
featlen	Numeric. Number of nucleotides on feature (exon) side of boundary.
gaplen	Numeric. Number of nucleotides on gap (intron) side of boundary.

unique	Logical. Default is 'FALSE'. When 'TRUE', the function removes duplicate entries which can be due to alternative splice events.
strand	Character. Mandatory. All strand entries are set to the given value.
...	Optional arguments passed additionally to the function (currently unused).

### Details

The functions are intended to provide position information which crosses exon-intron boundaries. Added DNA sequences can be used to produce seqlogs. The functions are intended to be used in advance of xCodons functions. Later on added AA sequences can be used to search for proteins where intronic sequences are retained.

### Value

cRanges

### Author(s)

Wolfgang Kaisers

### Examples

```
# A) Create gapSites object
bam<-system.file("extdata","rna_fem.bam",package="spliceSites")
reader<-bamReader(bam[1],idx=TRUE)
ga<-alignGapList(reader)
bamClose(reader)
ga

# B) Extract junction data
lj<-lJunc(ga,featlen=6,gaplen=6,strand='+')
ljm<-lJunc(ga,featlen=6,gaplen=6,strand='-')
rj<-rJunc(ga,featlen=6,gaplen=6,strand='+')
rjm<-rJunc(ga,featlen=6,gaplen=6,strand='-')
lrj<-lrJunc(ga,lfeatlen=6,rfeatlen=6,strand='+')
lrjm<-lrJunc(ga,lfeatlen=6,rfeatlen=6,strand='-')
```

---

xJuncStrand

*xJuncStrand methods: lJuncStrand, rJuncStrand, lrJuncStrand*

---

### Description

The term 'xJuncStrand' envelopes three functions: lJuncStrand, rJuncStrand and lrJuncStrand. All three functions take a gapSites object and return ranges which are restricted around align-gap (exon-intron) boundaries. The functions lJuncStrand and rJuncStrand return cRanges objects, the lrJuncStrand function returns a gapSites object. The resulting objects contain strand information which is copied from the input objects.

**Usage**

```
lJuncStrand(x, featlen, gaplen, ...)
```

**Arguments**

x	gapSites. Object from which the lJuncStrand values are calculated.
featlen	Numeric. Number of nucleotides on feature (exon) side of boundary.
gaplen	Numeric. Number of nucleotides on gap (intron) side of boundary.
...	Optional arguments passed additionally to the function (currently unused).

**Details**

The functions are intended to provide position information which crosses exon-intron boundaries. Added DNA sequences can be used to produce seqlogos. The functions are intended to be used in advance of xCodons functions. Later on added AA sequences can be used to search for proteins where intronic sequences are retained.

**Value**

cRanges

**Author(s)**

Wolfgang Kaisers

**Examples**

```
# A) Create gapSites object
bam<-system.file("extdata","rna_fem.bam",package="spliceSites")
reader<-bamReader(bam[1],idx=TRUE)
ga<-alignGapList(reader)
bamClose(reader)
ga

# B) Extract JuncStrandtion data
lj<-lJuncStrand(ga,featlen=6,gaplen=6)
ljm<-lJuncStrand(ga,featlen=6,gaplen=6)
rj<-rJuncStrand(ga,featlen=6,gaplen=6)
rjm<-rJuncStrand(ga,featlen=6,gaplen=6)
lrj<-lrJuncStrand(ga,lfeatlen=6,rfeatlen=6)
lrjm<-lrJuncStrand(ga,lfeatlen=6,rfeatlen=6)
```
